1    **Abstract**

2    Evidence reviews are a key mechanism for incorporating extensive, complex and  
3    specialised evidence into policy and practice, and in guiding future research. However,  
4    evidence reviews vary in scope and methodological rigour, creating several risks for  
5    decision-makers: decisions may be informed by less reliable reviews; apparently  
6    conflicting interpretations of evidence may obfuscate decisions; and low quality  
7    reviews may create the perception that a topic has been adequately addressed, deterring  
8    new syntheses (cryptic evidence gaps). We present a new approach, evidence review  
9    mapping, designed to produce a visual representation and critical assessment of the  
10   review landscape for a particular environmental topic or question. By systematically  
11   selecting and describing the scope and rigour of each review, this helps guide non-  
12   specialists to the most relevant and methodologically reliable reviews. The map can  
13   also direct future research through the identification of evidence gaps (whether cryptic  
14   or otherwise) and redundancy (multiple reviews on similar questions). We consider  
15   evidence review mapping a complementary approach to systematic reviews and  
16   systematic maps of primary literature and an important tool for facilitating evidence-  
17   based decision-making and research efficiency.

## 1    **Background**

2    Scientific evidence is central to effective environmental policymaking and practice but  
3    its use requires an appreciation of the reliability of the evidence base. Primary research  
4    forms the backbone of an evidence base; however, non-specialists may lack the  
5    resources or expertise to evaluate the appropriateness of methodology and data analysis  
6    in primary studies, and to identify trends and patterns across multiple studies.  
7    Furthermore, the inherent complexity and variability of natural systems combined with  
8    differences in study methods typically generates findings that can be selectively used to  
9    support particular conclusions [1, 2]. Against this backdrop, non-specialists seeking an  
10    overview of particular topics (e.g. decision-makers and researchers in other fields) are  
11    increasingly likely to rely on evidence reviews that synthesise evidence across the  
12    spectrum of primary literature related to a specific, policy-relevant question [3-6].  
13    Evidence reviews (hereafter also referred to as ‘reviews’) attempt to answer a specific  
14    question by aggregating and synthesising the results of primary studies and may include  
15    meta-analysis (statistical methods for combining the magnitude of the outcomes [effect  
16    sizes] across different data sets addressing the same research question [7]) and/or  
17    narrative synthesis (use of prose to summarise and draw conclusions from primary  
18    research which may be supplemented by the reviewers’ own experience and may  
19    include limited quantitative analysis [6]). Evidence reviews may or may not be  
20    conducted within the framework of systematic review methodology [8]. Reviews that  
21    only collect and configure the primary literature with respect to a broad question, such  
22    as systematic maps, are not considered as an evidence review in this context.

23    High quality evidence reviews can provide decision-makers (or their advisors) with  
24    quick and easy access to available evidence on a topic or question of interest. However,  
25    as with primary research, reviews can differ in the rigour of the methods and the

1 reliability of findings [e.g. 6, 9, 10-12], and subtle differences in scope may influence  
2 their applicability to a particular problem. Indeed, the majority of reviews in  
3 environmental science are not conducted according to predefined guidelines, but instead  
4 apply a range of methods that each promote or compromise reliability to varying  
5 degrees [e.g. 6]. Differences in methodological reliability amongst reviews on similar  
6 topics create several related risks for researchers and decision-makers:

- 7 (i) decisions may be informed by less rigorous and/or biased reviews because  
8 of a lack of systematic collation of reviews and subsequent appraisal of  
9 review quality;
- 10 (ii) apparently conflicting interpretations of evidence among reviews with  
11 similar scope may obfuscate decisions; and
- 12 (iii) no new or updated reviews are conducted on a topic, because researchers  
13 and decision-makers are unaware that the topic lacks a highly rigorous  
14 synthesis (cryptic evidence gaps [12]).

15 Clearly communicating the scope and reliability of an evidence-base to decision-makers  
16 and other end-users is therefore essential to ensure potential limitations in the conduct  
17 of the review(s) being considered are appreciated. However, in the absence of  
18 communication mechanisms tailor-made for use within decision-making processes this  
19 can be challenging. Indeed, difficulties in locating relevant evidence and assessing the  
20 reliability of information gathered are often amongst the main concerns highlighted by  
21 decision-makers [13].

22 Systematic review and systematic map methodologies were developed in part in  
23 recognition of the variable reliability of reviews [14, 15] and as an attempt to reduce  
24 these risks and provide high quality evidence synthesis and overviews for decision-

1 makers. Nonetheless, while systematic reviews are becoming more widespread in the  
2 environmental sector, not all conform to recognised standards [e.g. 16] and non-  
3 systematic evidence reviews still dominate the review landscape [17]. Moreover, in the  
4 medical sector, where systematic review terminology was coined and application of the  
5 methodology is most widespread [14, 15], the exponential rise in systematic reviews  
6 and meta-analyses have been dogged by criticisms that many do not follow full  
7 systematic review guidelines, are conflicted by pre-conceived opinions or financial  
8 motivations of the authors, and/or have been used to advance industry interests instead  
9 of good science [18]. With awareness and application of systematic review  
10 methodology expanding in the environmental sector, it is vital that ways to maintain  
11 and monitor methodological standards are developed and applied to ensure the  
12 objectivity, robustness and value of evidence reviews for decision-makers.

13 Tools for critically assessing the methodological reliability of individual reviews have  
14 developed in many sectors [see 19 and references therein], although limited techniques  
15 exist to meaningfully apply and integrate these assessment protocols to inform  
16 environmental policy. Similarly, in other sectors, methods to inform non-specialists on  
17 available evidence have developed [e.g. 20], but often focus on synthesising findings  
18 from the systematic review literature [21], or on describing and appraising systematic  
19 reviews and related impact evaluations [22, 23]. None are designed to describe and  
20 critically appraise the evidence review literature as a whole or explicitly consider  
21 studies that evaluate environmental outcomes arising from interventions. Accordingly,  
22 new methods to assess and communicate the reliability (including limitations of  
23 evidence and methodological rigour) and scope of all reviews, systematic and non-  
24 systematic, could represent a more viable alternative for summarising evidence reviews  
25 in the environmental sector. In response, we develop a method that we term ‘evidence

1 review mapping', to produce a critical overview of all reviews examining the  
2 effectiveness of a given intervention and/or impacts of human pressures and  
3 management (e.g. effects of fisheries, impacts of land-use change, effectiveness of  
4 conservation interventions, etc.). This overview includes a systematic assessment of the  
5 questions addressed by each review (i.e. scope and relevance) combined with a critical  
6 appraisal of review methods (reliability and risk of bias). Outputs from evidence review  
7 mapping are designed specifically to inform non-specialists and improve  
8 communication of the evidence base by identifying the most relevant and reliable  
9 reviews, and to assist future syntheses by highlighting gaps and redundancy (multiple  
10 reviews on similar topics) in the review literature. Evidence review maps are tailor-  
11 made for the environmental decision-making community, offering a communication  
12 tool that consists of matrices that summarise the quantity and methodological rigour of  
13 reviews on a range of related questions, together with a series of supporting tables that  
14 provide more detailed information on the reviews for each particular question. Evidence  
15 review maps therefore do not aim to answer a specific question but rather intend to  
16 enable end-users to quickly assess the volume of evidence on the question(s) of interest,  
17 and to obtain an overview of how reliable that evidence is.

18 Here, we describe how to construct evidence review maps to inform environmental  
19 policy and research, providing examples with reference to a study we undertook in  
20 conjunction with developing this methodology [12]. We propose that evidence review  
21 mapping offers a complementary approach to systematic reviews and systematic maps,  
22 and suggest that adoption of the methodology will facilitate evidence-based policy and  
23 practice in conservation and environmental science.

## 24 **Methodology - Evidence review mapping**

1 Our approach to evidence review mapping consists of the following steps: (1) define the  
2 overall question of interest, construct a series of more refined questions that consider  
3 key aspects of the overall question, and then design the search strategy; (2)  
4 systematically search and screen for relevant evidence reviews; (3) assess the scope of  
5 each evidence review against the questions defined in step 1; (4) critically appraise the  
6 methods of each evidence review using a standardised protocol (we use the  
7 Collaboration for Environmental Evidence Synthesis Assessment Tool – CEESAT  
8 [19]); and (5) construct the evidence review map(s). The production of an evidence  
9 review map integrates some core systematic review methods complemented by several  
10 novel approaches designed specifically to search for, collate, categorise, and  
11 communicate review articles. We provide a description of each stage below illustrated,  
12 where appropriate, with details adapted from Woodcock et al. [12] who examined the  
13 evidence review landscape for the question ‘What is the effectiveness of marine  
14 protected areas as a tool for mitigating the impacts of fisheries on biodiversity?’

15 1. Define the question of interest, construct a series of more refined questions, and then  
16 design the search strategy

17 To provide the framework for the evidence review map, the overall question of interest  
18 (i.e. scope of the map) should be established. As with systematic review methodology  
19 the question will largely determine the inclusion criteria for the reviews that form the  
20 evidence review map. Consequently, we recommend that a Population,  
21 Intervention/Exposure, Comparator, Outcome (PI/ECO) structure is used to ensure a  
22 clearly defined question is developed [8].

23 Evidence review mapping uses a hierarchy of questions to assess the scope of reviews:  
24 the overall question sets the scope of the map and a series of more refined questions

1 then establish the key areas of interest within the overall question. More refined  
2 questions may be separated into broad questions (considering one key area of interest)  
3 and specific questions (considering paired combinations of key areas, based on the  
4 Population, the Intervention/Exposure, and the Outcome Metrics). Figure 1 describes  
5 the question hierarchy framework illustrated with example questions from Woodcock et  
6 al. [12]. Compiling a comprehensive list of key areas of interest and their pairwise  
7 combinations generates the framework for the evidence review map (Figure 2). The  
8 number of refined questions represents a pragmatic trade-off between capturing the  
9 many potential influences on the overall question of interest and generating an  
10 unmanageably large number of specific questions. The scope of the evidence review  
11 map will therefore partly depend on the resources available. In addition, while  
12 researchers may undertake evidence review mapping independently to guide future  
13 studies, maps that are designed to inform policy should develop the evidence review  
14 map framework in consultation with stakeholders in order to ensure relevance through  
15 appropriate selection of the Population, Intervention/Exposure, and Outcome Metrics to  
16 consider.

17 Together with the question, it is important to explicitly document the criteria for  
18 deciding on whether or not articles are relevant to include to ensure objectivity,  
19 transparency and repeatability during article screening. Once these have been defined,  
20 an appropriate search strategy should be developed and detailed within an *a-priori*  
21 protocol. The search strategy should draw on search methods used for systematic  
22 reviews [8] with the search effort depending on the scale of the evidence review map,  
23 the volume of subject-specific evidence, and the resources available. Topic-specific  
24 search strings should then be narrowed to focus on review articles using terms such as  
25 ‘AND (review OR "meta-analy\*" OR synthes\*)’ or using appropriate database filters

1 for 'review articles' if available and known to be reliable, and the databases that will be  
2 searched should be documented [see 8 for further information on search strategy design  
3 and reporting]. Note that in sectors where systematic reviews are more widespread,  
4 search filters designed to retrieve research by study design or focus have been heavily  
5 invested in (e.g. [https://sites.google.com/a/york.ac.uk/issg-search-filters-](https://sites.google.com/a/york.ac.uk/issg-search-filters-resource/home)  
6 [resource/home](https://sites.google.com/a/york.ac.uk/issg-search-filters-resource/home)). While similar filters exist within search engines commonly used by the  
7 environmental sector (e.g. Web of Science, Scopus) this functionality is less well-  
8 developed and database-specific so caution is recommended before relying solely on  
9 their use.

## 10 2. Systematically search and screen for relevant evidence reviews

11 A systematic search and screening process to identify relevant articles should be  
12 undertaken in line with systematic review guidelines [8], with searches  
13 comprehensively documented and the repeatability of inclusion decisions during  
14 screening tested using a kappa test of agreement [24, 25] or similar. Inclusion criteria  
15 should be refined as necessary to ensure repeatability [8]. Articles assessed for  
16 relevance at full text should be clearly documented in the supporting tables to the map  
17 (see step 5) with the reasons for exclusion provided where appropriate to maintain  
18 transparency. Importantly, in some instances, reviews that are excluded may contain  
19 related information of potential interest (e.g. outside the taxonomic or geographic scope  
20 of the evidence review map), or partially consider some questions of interest as part of a  
21 broader-ranging review with a different scope (this can occur particularly for narrative  
22 reviews). Note also that some studies use meta-analytical techniques in the analysis of  
23 long-term primary data [e.g. 26] or data from selected case studies [e.g. 27] rather than  
24 with the aim of comprehensively synthesising published research. As these would not  
25 be expected to follow all of the methods required to produce a rigorous review of

1 primary research (e.g. *a-priori* protocol, comprehensive searching, screening), they are  
2 unsuitable for evaluation using CEESAT. However, marking such reviews as  
3 ‘borderline relevant’ can assist decision-makers seeking additional information.  
4 Included articles can be assigned a number (meta-analyses) or letter (narrative  
5 syntheses) to act as a unique identifier when constructing the evidence review map and  
6 these should be documented in supporting tables (e.g. Table 1a).

### 7 3. Assess evidence review scope

8 Constructing an evidence review map requires that each relevant review is  
9 systematically categorised according to the question(s) addressed (as defined in step 1)  
10 and the type of synthesis undertaken (e.g. narrative/qualitative [which may include  
11 limited quantitative analyses] or meta-analyses; see [6] for definitions of each). Note  
12 that multiple questions are often addressed within a single review, and so a single  
13 review may be included several times in an evidence review map. The extent to which  
14 scope can be objectively categorised is influenced by the methods employed in the  
15 review. Whilst a meta-analysis can usually be objectively categorised as addressing a  
16 particular question based on whether or not effect sizes are presented, there is no such  
17 obvious distinction in many narrative reviews, in which questions could be addressed  
18 through varying amounts of text with varying degrees of relevance and supporting  
19 references. This problem is exacerbated because the scope of narrative reviews is often  
20 broader than meta-analytical reviews. Reliable categorisation of scope is thus possible  
21 in greater detail for meta-analyses than for narrative syntheses. The assessment of  
22 review scope should therefore be undertaken in two parts, firstly considering reviews  
23 that apply meta-analytical techniques and secondly reviews that use narrative synthesis.

1   Categorisation of meta-analyses as addressing particular questions requires effect sizes  
2   to be quoted directly, presented graphically or used in statistical tests of relationships  
3   [12]. Instances where relevant terms are included as potential confounding variables but  
4   statistics (e.g. effect sizes) are not reported would not be considered as directly  
5   addressing a given question [12]. A threshold for the minimum number of primary  
6   studies a meta-analysis must contain to be categorised as addressing a particular  
7   question could be set. The minimum threshold is highly context-specific (e.g. relating to  
8   the quality of primary research, typical effect sizes and variances, etc.) and  
9   consequently requires a transparent case-by-case judgement for each evidence review  
10   map. Where a threshold is considered appropriate, reviews that do not meet this  
11   threshold should be noted as partially addressing the question, thereby allowing articles  
12   that are based on a small volume of primary research to be identified.

13   Categorisation of narrative syntheses should be undertaken wherever possible using the  
14   refined questions initially devised in step 1. However, because narrative syntheses often  
15   cover a range of topics in varying depths, such fine-scale categorisation may not be  
16   possible and so questions may need to be broadened to more accurately reflect narrative  
17   review content (e.g. by broad area of focus etc. see Figure 3 and [12]).

18   4. Critically appraise the methods of each evidence review using a standardised  
19   protocol

20   The assessment of review methodology forms the penultimate stage in evidence review  
21   map development. A standardised protocol designed to assess the reliability of  
22   environmental evidence reviews should be utilised to critically appraise the  
23   methodological rigour of each relevant review in a consistent manner. For this purpose  
24   we recommend the Collaboration for Environmental Evidence Synthesis Assessment

1 Tool [CEESAT; 19]. The current version of CEESAT (available at  
2 [www.environmentalevidence.org/review-appraisals](http://www.environmentalevidence.org/review-appraisals)) consists of 13 criteria relating to  
3 the reliability (combining objectivity, transparency, and comprehensiveness) of reviews  
4 [see 19 for details], and achieves good repeatability when independent assessments of  
5 the same review are compared [6, 12, 19]. For each criterion, reviews receive 3 points,  
6 1 point, or 0 points. Scores therefore range from 0-39: the higher the score, the greater  
7 the confidence that the review methodology is robust and reliable in terms of  
8 repeatability and risk of bias. Importantly, while certain criteria within CEESAT require  
9 statistical analysis to score highly, points for these criteria are available to narrative  
10 syntheses [6, 19]. Furthermore, high scores are available equally to narrative syntheses  
11 and meta-analyses for most of the criteria enabling narrative syntheses to be assessed as  
12 having high reliability (a score of 26.5+) where appropriate [e.g. see 6]. Reviews should  
13 be independently scored by two assessors and the repeatability of the assessment  
14 evaluated with a weighted kappa test of agreement [24, 25] or similar to take into  
15 account the magnitude of any disagreements, e.g. a 1-0 disagreement is ranked as  
16 magnitude 1, whereas a 3-0 disagreement is ranked as magnitude 3 [10, 28].  
17 Disagreements between assessors should be discussed and where these reflect  
18 uncertainty over whether or not a criterion was met, the average score from the two  
19 assessors should be used.

20 There are a number of possible approaches to interpreting CEESAT scores [see 19 for  
21 further discussion] however, we currently recommend dividing total CEESAT scores  
22 into three categories 0-13, 13.5-26 and 26.5+, loosely representing low,  
23 intermediate/moderate and high methodological reliability. The boundaries for these  
24 categories reflect an average score across the 13 criteria of 0-1, 1-2 and 2-3. Note that  
25 while these boundaries may change as further guidance on scoring interpretation

1 becomes available, or if certain aspects of review conduct are prioritised by those  
2 conducting an evidence review map, the methodology for incorporating scores into  
3 evidence review mapping will remain valid.

#### 4 5. Construct the evidence review map

5 Finally, using information from steps 3 and 4, a series of evidence review maps may be  
6 constructed to visually represent the review landscape for the overall question of  
7 interest (Figure 3). Separate maps should be constructed to describe meta-analyses and  
8 narrative reviews to ensure similar levels of objectivity in review categorisation within  
9 each map. Evidence review maps should be constructed using refined questions as  
10 defined in step 1 for meta-analyses and those determined in steps 1 and/or 3 for  
11 narrative reviews. Note that for the example here, none of the narrative syntheses  
12 provided sufficient information to score highly when assessed with CEESAT [e.g. see  
13 12] and, as a consequence, the narrative evidence review map shows all reviews to be  
14 of low reliability (Figure 3b). This reflects the specific evidence base for MPA  
15 effectiveness rather than being a consequence of differences in the way in which  
16 CEESAT evaluates narrative syntheses vs. meta-analyses [12].

17 Evidence review maps consist of a matrix that combines information on the number of  
18 reviews addressing a given question and the methodological rigour of each review,  
19 enabling end-users to see what evidence there is on the question(s) they are interested  
20 in. The matrix overview is supported by a series of tables that allow the most rigorous  
21 reviews on each question to be identified. The matrix should be read using  
22 combinations from the top and left headings to form a particular question. Doughnut pie  
23 charts can be created to represent (1) the total number of reviews that address each  
24 individual question (included in the centre of the doughnut pie) and (2) the proportion

1 of those reviews that are of high, medium or low methodological reliability. Symbols  
2 should be used to identify where reviews have been categorised as partially addressing  
3 a particular question (due to the threshold for number of included primary research  
4 articles not being met). The format of the matrix means that some questions will not be  
5 applicable; these areas should be left blank. Full details of reviews included for each  
6 specific question, together with details of any reviews that partially address a given  
7 question should then be provided in a series of supporting tables (e.g. see Table 1b and  
8 c and [12]).

9 Supporting tables should include: (1) details for the search strategy; (2) a list of relevant  
10 reviews with their unique identifier and review score; (3) a list of excluded studies with  
11 reasons for exclusion; and (4) a series of tables detailing the meta-analyses and  
12 narrative syntheses examining each refined question, designed to direct end-users to the  
13 most relevant and rigorous review for their requirements.

## 14 **Discussion**

15 Understanding the reliability of an evidence base is central to effective decision-making  
16 and developing mechanisms for communicating this to decision-makers is therefore  
17 essential. While systematic review methodology is considered a key tool for unbiased  
18 evidence synthesis, the reliability of evidence reviews will continue to vary for many  
19 reasons [18]. With the number of reviews of all types continuing to increase, evidence  
20 review maps provide the opportunity to visualise the review landscape for an overall  
21 question of interest and to guide non-specialists to more relevant and reliable reviews.  
22 We consider evidence review mapping a complementary approach to systematic  
23 reviews and systematic maps and an important tool for facilitating evidence-based  
24 decision-making.

1 Evidence review mapping relies on systematic searching, transparent decisions on  
2 article inclusion and exclusion, objective assessment of review scope and a standardised  
3 and repeatable protocol for critically appraising individual reviews. Application of our  
4 approach has illustrated the variable scope and reliability of published evidence reviews  
5 and the need to ensure non-specialists can locate the most relevant and rigorous reviews  
6 on particular questions of interest, as well as indicating how planned reviews can be  
7 designed to complement the existing body of reviews [12]. We believe this approach  
8 and its outputs will be useful to decision-makers, advisors and knowledge brokers  
9 wishing to use evidence in environmental policy and practice, as well as to researchers  
10 looking to contribute to the evidence base through targeted evidence synthesis. Our  
11 approach to evidence review mapping could be applied widely to many important  
12 questions in environmental policy, as an ‘evidence service’ with considerable benefits  
13 for research efficiency and evidence-based policy.

#### 14 Considerations for conducting evidence review maps

15 While evidence review mapping is a valuable tool, it will pose some challenges to those  
16 wishing to construct such maps. Most notably, decisions over whether or not reviews  
17 are relevant for inclusion require subjective judgement. This difficulty arises  
18 particularly in narrative syntheses, because there is a continuum between studies that  
19 exclusively review the findings from relevant primary research versus studies that have  
20 a very broad scope or a more conceptual focus and are therefore less appropriate for  
21 evidence review mapping. Because most subjective decisions on relevance relate to  
22 narrative reviews, altering these decisions would not affect the meta-analytical evidence  
23 review map and, while they might adjust the average narrative review score for a given  
24 question, they are unlikely to markedly change the conclusions on review rigour and  
25 scope. Nonetheless, ensuring transparency of decisions at all stages of evidence review

1 mapping by documentation in the supporting tables is an important component of the  
2 methodology to enable end-users to understand and challenge the decisions made over  
3 article inclusion and categorisation. Additionally, some methodologically distinct forms  
4 of review, such as qualitative syntheses or mixed methods may not be suitable for  
5 appraisal using CEESAT and including such reviews will require further research and  
6 development.

7 Evidence review maps rely on the use of a standardised scoring tool to assess the  
8 reliability of reviews. Like other scoring tools, CEESAT assesses the likelihood that a  
9 review is reliable on the basis of key attributes relating to available evidence, conduct  
10 and reporting standards, and does not guarantee the reliability of a review against other  
11 factors such as author errors. In addition, total scores of reviews can mask specific  
12 strengths or weaknesses across criteria. A breakdown of scoring across individual  
13 criteria may therefore be a useful subsequent output to ensure that decision-makers can  
14 gauge the extent to which the strengths and weaknesses of a review make it suitable for  
15 the intended use [see 19 for a detailed discussion of important caveats in applying and  
16 interpreting CEESAT scores]. Researchers who wish to undertake evidence review  
17 mapping may wish to use alternative boundaries and/or weightings of criteria to  
18 represent reliability than those suggested here if certain aspects of review conduct are  
19 viewed as particularly important to the end-user. In such instances, clear rationale for  
20 amending these boundaries and/or weightings should be provided as part of the  
21 evidence review map.

22 There may be instances in which more than one high scoring review addresses a  
23 particular question. In such situations, further assessment could consider the  
24 consistency in findings between reviews (noting that direct comparisons of specific  
25 results can be misleading if subtle differences in review scope are not identified). If

1 results differ between reviews, potential reasons for ambiguity could then be  
2 considered, and further work targeted to examine the evidence base where reasons for  
3 discrepancy are unclear. In the latter situation, systematic reviews, containing meta-  
4 analytical techniques wherever possible, and/or targeted and well-designed primary  
5 research are recommended to ensure that policymaking is informed by reliable evidence  
6 that is robust and methodologically rigorous [29].

7 Finally, note that unlike ‘review of reviews’ that aim to provide a synthesis of evidence  
8 from more than one review, evidence review maps do not set out to answer a specific  
9 question but rather seek to provide an overview of the existing review evidence base.  
10 Consequently, maps are intended to guide decision-makers to relevant information and  
11 illustrate strengths and weaknesses in the evidence base, rather than to directly provide  
12 policy recommendations or guidelines. Future work that may add value to evidence  
13 review maps might include developing user-friendly summaries on included reviews, or  
14 reports summarising the findings of the evidence review map together with implications  
15 for policy and research.

## 16 **Conclusions**

17 As the review literature continues to expand, it will become increasingly difficult for  
18 non-specialists to locate all relevant evidence reviews. Furthermore, when selecting  
19 reviews to inform decision-making, non-specialists may lack the resources to critically  
20 appraise all available syntheses and may instead treat all evidence reviews equally, or  
21 use measures of review rigour that are questionable and/or subjective (e.g. journal  
22 impact factor, citation count, author reputation). However, we, and others [e.g. 6, 9, 12,  
23 30], have found that published evidence reviews in the environmental sector vary  
24 considerably in reliability and scope, which presents challenges to those wishing to

1 undertake evidence-based decision-making. We therefore propose that evidence review  
2 mapping represents an important method for communicating the reliability and scope of  
3 all reviews on a particular topic to non-specialists, thereby facilitating evidence-based  
4 policy and practice in conservation and environmental science.

## 5 **Declarations**

6 Ethics approval and consent to participate: Not applicable

7 Consent for publication: Not applicable

8 Availability of data and material: All data generated or analysed during this study are  
9 included in the published article Woodcock, P., O’Leary, B.C., Kaiser, M.J., Pullin,  
10 A.S. (in press) Your evidence or mine? Systematic evaluation of reviews of marine  
11 protected area effectiveness. Fish and Fisheries. <http://dx.doi.org/10.1111/faf.12196>  
12 (and its supplementary information files).

13 Competing interests: The authors declare that they have no competing interests"

14 Funding: This work was supported in part by a UK Natural Environmental Research  
15 Council Knowledge Exchange Grant NE/J006386/1. No other grants from funding  
16 agencies in the public, commercial, or not-for-profit sectors were received.

17 Authors' contributions: Led the research: BCO, PW, ASP. Wrote and reviewed the  
18 manuscript: BCO, PW, MJK, ASP. All authors read and approved the final manuscript.

19 Acknowledgements: We thank our potential end-users Ally Dingwall (Sainsbury’s),  
20 Tom Pickerell (Seafish, Seafood Watch), Jon Harman (Seafish), Mike Mitchell, David  
21 Parker (Young’s Seafood), David Jarrad (Shellfish Association of Great Britain) for  
22 their contribution to discussions regarding review reliability. This project was supported

1 in part by a UK Natural Environmental Research Council Knowledge Exchange Grant  
2 NE/J006386/1.

## 1 **Figure Legends**

2 **Figure 1.** Question hierarchy framework used to assess the scope of reviews for  
3 evidence review mapping. Descriptions of the purpose of each question level are  
4 provided to the left of the triangle. Example questions based on Woodcock et al. [12]  
5 illustrating each level of questioning are provided to the right of the triangle.

6 **Figure 2.** Schematic illustrating the process of constructing the framework for an  
7 evidence review map. Example evidence review map explores the effectiveness of  
8 marine protected areas (MPAs) for biodiversity conservation. Key components of the  
9 overall question are identified in the left panel (e.g. Population: regional and taxonomic  
10 focus, Intervention: aspects of MPA design considered, Outcome: outcome metrics used  
11 to assess MPA effectiveness). In the panel on the right, these components are combined  
12 to construct the framework for the evidence review map consisting of broad (dark grey  
13 boxes) and specific (light grey boxes) questions. White boxes indicate questions that are  
14 not applicable, e.g. Global/Temperate question combinations. Abbreviations in  
15 headings refer to: Taxa – Invert=invertebrates, MPA Char=MPA Characteristics,  
16 Outcome Measures - Abund=abundance. Example adapted from Woodcock et al. [12].

17 **Figure 3.** Example (a) meta-analytical and (b) narrative evidence review map  
18 illustrating the marine protected area review landscape. The matrix should be read using  
19 combinations from the top and left headings to form the particular question of interest.  
20 Each individual doughnut chart describes the number of reviews addressing a question,  
21 and the proportion of reviews that are high (26-5+; black), moderate (13.5-26; grey) and  
22 low ( $\leq 13$ ; white) scoring. Star symbols represent where one or more reviews have been  
23 identified that partially address the particular question. Full details identifying reviews  
24 that address a particular question are reported in the supporting tables. Abbreviations in

headings refer to: Taxa – Invert=invertebrates MPA Char=MPA Characteristics,  
 Outcome Measures - Abund=abundance, Broad Focus – BD-biodiversity,  
 Fish=Fisheries. Example adapted from Woodcock et al. [12].

## Tables

**Table 1.** Example evidence review map supporting tables (a) reviews assessed as relevant for inclusion, with review score, (b) scope of meta-analyses that examine broad questions: region, taxa, MPA characteristic and outcome measure, and (c) scope of narrative syntheses that examine the specific question: broad focus and region. Superscript Roman numerals adjacent to ‘Scope’ in (b) are used to refer the end-user to relevant notes on additional reviews that consider the question but with less than the required number of primary studies or without reporting effect sizes. Example adapted from Woodcock et al. [12].

a)					
	Review Number	Reference	CEESAT Score		
	I	Meta-analytical reference			
	a	Narrative reference			
b)			c)		
	Scope	Review number		Scope	FOCUS
Region	Global	3, 6-9, 11-14, 16, 17			Biodiversity Fisheries
	Tropical <sup>i</sup>	8, 10		Global	b, c, f, h, i b, e, f, g, h, i
Taxa	Fish <sup>ii, iii, iv</sup>	1-3, 5, 6, 8, 10-18	Region	Temperate	d d
	Invertebrate <sup>ii, iii, iv</sup>	6, 8, 15, 16, 18		Tropical	a
MPA	Size <sup>i, vi</sup>	1-3, 5, 6, 8, 10, 11, 15, 17, 18			
Characteristic	Age <sup>v</sup>	1-3, 5, 7, 10-13, 15, 17, 18			
Outcome Measure	Abundance	1-18			
	Biomass <sup>vii, viii, ix</sup>	4-8, 17, 18
